Potential competing interests: No potential competing interests to declare.

Therapeutic effects of PRP are well proven. The only drawback is the extracted quantity is very less. Moreover, the PRP, PPP or fibrin mesh disintegrates within 48 to 72 hours, leaving the bone graft particles dispersed at the site of application. Their results are very predictable in the areas where the primary closure of the wound is possible. I am not convinced by the use of fibrin mesh for covering the defects. I feel the necessity of mention of defect sizes which you included in this study.
