Potential competing interests: No potential competing interests to declare.

The latest version is improved. Still, in section 3 - Results, it is important to clarify what the research variables are, what the PLS test is, and to clarify whether there are 45 participants or 45 samples (it seems to me that there is confusion on this subject). Before analyzing the results, it is important to present and explain what the variables of interest are and what will be evaluated.

Levene's test evaluates whether or not the variations are homogeneous between 2 groups. It is not clear how the result of this test allows us to conclude "the use of greenery is the same among males and females and also is the same among different age groups."

After that, I consider the discussion and conclusions can be revised after resolving and reevaluating the data and results obtained.
