Generally it is a very detailed review of a complex subject with an increasingly large literature.

I was disappointed that they did not go into a more detailed review of the issue of bone turnover as demonstrated by bone markers. Although it's not clear cut there is some merit in using CTX at least for research if not clinical guidance. I would also draw the authors' attention to our large prospective clinical study on extractions for osteoporotic patients on denosumab. Collela *et al.* JOMS 2023. From that we agree that extractions best left to 6 months after the last injection of denosumab. We would certainly avoid extractions after only 3 weeks after the last injection. At that stage the bone turnover is still very low.

Apart from these minor comments it's an excellent contribution to the world literature.
