Dear Editor:

This article has many merits. There are a large number of cases, and secondly, the relationship between smoking and emotions is analyzed from multiple dimensions. From a statistical perspective, it has certain scientific significance.

But this article also has some problems. First of all, people of different ages may have different experiences with smoking. Young people enjoy smoking more, and as age increases, the amount of daily smoking increases. At the same time, the physical discomfort caused by smoking is also increasing, and there are even tobacco dependence-related diseases. Therefore, compared with middle-aged and elderly people, young people have different experiences with smoking. Many young and middle-aged men smoke no less than middle-aged and elderly men. Compared with middle-aged and elderly men, the mood of young and middle-aged men seems to be more optimistic. It can be seen the factors affect mood are composed of many aspects. It is difficult to analyze whether the amount of smoking will affect the mood. On the other hand, has two extremes. First of all, on the one hand, it is often related to the work of smokers. For example, people who often work night shifts smoke significantly more. The smoker's experience at this point is not pleasant. On the other hand, some smokers are cheerful and comfortable, but often have social activities and social interactions. The increased desire to smoke caused by drinking alcohol also leads to an increase in daily smoking highlights. Therefore, the author can analyze the relationship between the work, life characteristics and emotions of several different smoking groups based on different occupational attributes and social activities and communication characteristics.
