Self-healing papular mucinosis

INSERM

Source

INSERM. (1999). *Orphanet: an online rare disease and orphan drug data base*. [Self-healing papular mucinosis](#). ORPHA:90397

Self-healing papular mucinosis is a rare form of localized lichen myxedematosus (see this term) occurring primarily in children and characterized by the development of mucinous papules on various parts of the body (face, neck, trunk, and limbs) that resolve spontaneously within some weeks to months. Systemic symptoms can be observed such as fever, arthralgias and weakness.
