INSERM. (1999). *Orphanet: an online rare disease and orphan drug data base. Localized lichen myxedematosus with monoclonal gammopathy or systemic symptoms. ORPHA:90399*

Localized lichen myxedematosus with monoclonal gammopathy or systemic symptoms is a form of atypical lichen myxedematosus (see this term), characterized by the appearance of several 2-4 mm erythematous waxy papules confined to a few sites that may be associated with either an immunoglobulin A (IgA) nephropathy in patients with acral persistent papular mucinosis; discrete papular lichen myxedematosus (see these terms); a scleromyxedema-like involvement, with dysphagia, hoarseness, pulmonary involvement, and carpal tunnel syndrome; myositis without skin sclerosis; or paraproteinemia.
