Meanwhile, capacitors have a longer life and can be discharged quickly, but store much less total energy. To make nanostructured arrays of electrostatic capacitors. A nano supercapacitor can be created. Electrostatic nanocapacitors are the simplest type of electronic energy storage device. They store electrical charge on the surface of two metal electrodes separated by an insulating material. The storage capacity of the electric nano supercapacitor is directly proportional to the surface area of these sandwich-like electrodes.

The storage capacity of the electric nano supercapacitor can be increased by using nanostructures to increase the level of energy storage. The electrodes of the nanoelectric supercapacitor work like the electrodes in regular capacitors, but instead of being flat, they are tubular and collect in the depth of nano cavities.
