The following article is nicely written and well presented. However, I would like to make some observations about this paper.

1. While mentioning some recommendations, why can't they be more experimental and analytically based?
2. Recommendations based on the soil improvement solutions can either be proven with geotechnical lab experimentation, results with graphs, tables, and analysis with the use of geotechnical software.
3. Solutions for the structural impacts can be suggested with the use of various structural-based tests in the lab and also by using analytical software to understand structural behavior.
