Review of: "Metabolic Intervention with Glucosodiene: Follow-up Insights on Successful First Case Treatment for Metastatic Triple Negative Breast Cancer (TNBC) of Bone after a Four Month Treatment Duration"

Yuying Tan

Potential competing interests: No potential competing interests to declare.

The presented article on metabolic intervention treatment for TNBC patients is intriguing due to its potential anti-tumor effects and apparent safety. The exploration of metabolic interventions in cancer treatment is a promising avenue, as highlighted in this single case report. However, to enhance the comprehensiveness of the study, it would be beneficial to include specific details regarding the rationale for selecting this method for the particular patient under consideration.

In particular, the inclusion of metabolic features such as glucose levels and information about any pre-existing metabolic conditions, such as diabetes, in this patient would provide valuable context. Understanding the metabolic profile of the patient can shed light on whether there were specific metabolic characteristics that influenced the choice of this intervention. This information is crucial for researchers and clinicians aiming to extrapolate the findings to a broader population and to discern the potential applicability of metabolic interventions in cancer treatment.

By elucidating the metabolic background of the patient, the study could contribute significantly to the field by addressing the question of whether this method is universally applicable to all cancer patients or if its efficacy is influenced by the presence of other metabolic diseases. This clarification is essential for guiding future research and clinical applications of this novel cancer treatment. Including such details will not only strengthen the current study but also facilitate a more nuanced understanding of the broader implications of metabolic interventions in diverse cancer patient populations.
