The latest version is improved. Still, I think that some things can still be improved. Starting with section 3 - Results. It is important to clarify whether there are 45 participants in the study or 45 samples to be tested and analyzed. It should also be explained what the PLS test is.

Levene's test aims to assess whether or not the variances between two groups are homogeneous. As such, it is not clear why the statement "the significance level of the test for the variance is more than 0.05, so the use of greenery is the same among males and females and also is the same among different age groups."

After that, the discussion and conclusions can be revised after resolving and reevaluating the data and results obtained.
