Meaningful and important work has been done. Here, health risks could be reviewed and physical risks could be included in the study. Outliers in the age group may also have affected the results of the study. It is important to evaluate the effects of gender, age and economic status together with a regression analysis. Variables like 'the situation of living with the family, the situation of staying at home,' etc. could also be explored. In general, many confounding factors were left out in the study. Moreover, the net effect of the given variables could not be evaluated.
