Potential competing interests: No potential competing interests to declare.

Each of these two early biosensors used a different transducer in its signal conversion section. In the first type, blood sugar was measured by measuring the electric current generated (ammetric), while in the urea sensor, the urea concentration was measured based on the electric charge created by the sensors (Potentiometric) may someday allow the patient to detect diseases without having to visit a doctor and only on the basis of information that a COBD or Doctor-Board-on-Chip provides, the type of disease has been detected. And then it is injected into the blood. This will drastically reduce the dosage of the required drugs and mitigate the side effects of the Effect-Side drug, because the drug dosage is very low and is also sent to the required place in the body.

The drug acts directly on a biosensor that converts the biological response into an electrical signal and consists of two main components: the receptor and the detector.
