## Source

INSERM. (1999). *Orphanet: an online rare disease and orphan drug data base. Benign partial epilepsy with secondarily generalized seizures in infancy. ORPHA:166302*

Benign partial epilepsy with secondarily generalized seizures in infancy is a rare infantile epilepsy syndrome characterized by seizures presenting with motion arrest and staring. They are followed by generalized tonic-clonic convulsions with normal interictal EEG and focal paroxysmal discharges, followed by generalization in ictal EEG. Seizures usually occur in clusters and are responsive to treatment. Psychomotor development is normal.
