The topic is interesting, and it is publishable. But I have the following concerns.

1-The presentation of the equations should be improved.

2-The authors stated that "each focal element's beliefs contribute equally to the similarity measure, which is unreasonable", which is an important factor of the proposed method. I further wonder why it is unreasonable, and if there exist related studies have demonstrated this.

3-It needs to further clarify why the Gaussian kernel function is used to design the proposed method.
