This study provides an interesting point of view regarding how SARS-CoV-2 infection can cause neurological problems, hence the new challenges on how to diagnose and treat them properly. Although further studies about the pathophysiology of the disease, how to diagnose, and the proper treatment need to be done, the discussion can be improved by adding the exact data regarding the incidents of cerebrovascular events in COVID-19 patients. In addition, the writer can also provide the characteristics of the patients who experienced cerebrovascular events after SARS-CoV-2 infection. The writer can also discuss the most frequent symptoms to raise awareness and highlight what needs to be noticed by doctors or medical workers. The writer has already mentioned the use of prophylactic treatment such as Aspirin and Clopidogrel. However, which kind of patients needs this prophylactic treatment has not been discussed. Further analysis of the risk factors for having cerebrovascular events, such as intrinsic factors of the patients and COVID-19 severity, as a complication of the infection can also strengthen the conclusion.
