Infantile digital fibromatosis

INSERM

Source

INSERM. (1999). *Orphanet: an online rare disease and orphan drug data base. Infantile digital fibromatosis. ORPHA:199267*

Infantile digital fibromatosis is a rare, benign, superficial fibromatosis characterized by firm, pinkish to flesh-colored, solitary or multiple nodular growths, typically less than 2 cm in size. They occur on the dorsal or lateral aspect of fingers and toes and have a tendency to recur. Histology reveals bland intradermal spindle cells with spherical perinuclear inclusion bodies.
