Dear Editor,

I went through this article critically, and the following are my queries.

1. Please see Table 1:

- a. Check the total under the age group. It is more than the total samples collected.
- b. The class range within age should be equal, viz., 0 -15, 16 -30, 31-45, 46 -60, and 61+.
- c. Under gender, what comes under others? Kindly explain. Is it transgender? Its proportion among long COVID cases seems too high.
- d. Under comorbidities, the total samples were 2770. What is the condition of the balance 370 sample cases? Describe their age, gender, and ethnicity.
- e. 2. In my opinion, older age groups should have increased odds of long COVID than the young age group, which is in contrast to your results.

Kindly do the needful to answer my queries.
