The article "Assessment and Improvement of Nutritional Knowledge among Hospitalized Cancer Patients: Gaps, Sources, and Educational Strategies" by Qiu Yan provides an insightful and comprehensive examination of the current state of nutritional knowledge among cancer patients. It addresses critical gaps and offers strategic solutions for improvement. The study's findings on the impact of demographic factors and the predominant reliance on informal, unreliable sources for nutritional information emphasize the need for structured, healthcare professional-led education. Furthermore, the call for the development of validated assessment tools to measure patients' nutritional knowledge is both timely and crucial. This work is exceptionally well-structured, deeply analytical, and significantly contributes to the field of oncology and patient care. It highlights the urgent need for integrated approaches in patient education and underscores the vital role of personalized nutritional guidance. I strongly recommend this paper for direct publication without revisions, as it is a substantial addition to the academic discourse and has the potential to influence both policy and practice in healthcare settings.
