The authors presented an interesting topic on the Design of Experiment method in fatigue analysis. It is a valuable topic for engineers. The authors give a new look to the design of mechanical components. The article is well organised. However, it is surprising that the authors used a stress fatigue model. In my opinion, the fatigue life model will be more suitable because it calculates the number of cycles for an established stress. Additionally, it is wondered why the authors did not use weight as a criterion, which is important in the design process of aeroplanes.
