Dear Authors

Covid infection actually leads to hypercoagulability and vascular inflammation with the appearance of retinal vasculitis. The difficulty of making such an early diagnosis was determined by the impossibility of evaluating patients in the initial stages of the disease due to their isolation and poor general condition.

It is a properly written article.

I have a few remarks:

The results do not provide much information about the diagnosis and treatment of vascular disease. At what interval since the Covid infection, and how was the diagnosis made?

Are there limitations of this study?

More concise conclusions.
