Potential competing interests: No potential competing interests to declare.

The article presents a well-structured study on the impact of faecal microbiota transplantation (FMT) on patients with recurrent *Clostridioides difficile* infection. Here are my few comments:

1. The methods section is quite comprehensive, but could you provide details on the criteria used for selecting the patient cohort and any exclusion criteria that may have influenced the study outcomes?
2. Could you incorporate the details of the study design into the methodology section?
3. The study suggests that the recipients resistomes became more donor-like over time. Could you discuss the potential clinical implications of this finding and how it might influence future FMT protocols?
4. What are the potential limitations of your study, and how might they impact the interpretation of your results?
