The study "Assessment and Improvement of Nutritional Knowledge among Hospitalized Cancer Patients: Gaps, Sources, and Educational Strategies" presents an important and comprehensive exploration of the critical gaps in the nutritional knowledge of hospitalized cancer patients. It insightfully identifies demographic factors and the lack of credible information sources as key barriers to effective nutritional education. The manuscript thoroughly evaluates the current tools for assessing nutritional knowledge and suggests the need for validated, universally recognized instruments to aid in this process. Furthermore, the research emphasizes the urgent need for healthcare professionals to be more actively involved in delivering accurate and reliable nutritional guidance. Given its well-structured analysis, significant findings, and potential for profound impact on cancer care, I strongly recommend this study for direct publication without the need for further revision. The study is meticulously researched, well-articulated, and contributes meaningfully to the field, highlighting the necessity of integrating nutritional education into cancer patient care to enhance outcomes and quality of life.
