Schisis association

INSERM

Source

INSERM. (1999). Orphanet: an online rare disease and orphan drug data base. Schisis association. ORPHA:63862

Schisis association describes the combination of two or more of the following anomalies: neural tube defects (e.g. anencephaly, encephalocele, spina bifida cystica), cleft lip/palate, omphalocele and congenital diaphragmatic hernia (see these terms). These anomalies are associated at a higher frequency than would be expected with random combination rates.
