Dear author, thank you for inviting me to review the manuscript. It is very interesting.

The abstract of "Mollusum Contagiosum: Case Report in A 10-Year Period (2008-2017)" presents a concise overview of the study, highlighting its objective, methodology, and key findings. Here's a review of the content:

Objective: Clearly stated at the beginning of the abstract, the objective is to present a series of 10 cases of Mollusum contagiosum (MC) over a 10-year period and compare the progression of the disease with and without treatment. This sets a clear direction for the study.

Materials and Methods: The abstract briefly outlines the methods used in the study, including anamnesis, clinical examination, and photography with patient consent. While it provides a general overview, more detail about the methodology could enhance clarity.

Results: The abstract summarizes the key results, including the average age and parity of the cases, the presentation of lesions, associated conditions like abnormal vaginocervical cytology and HPV, and the outcomes of treatment. This section effectively highlights the main findings of the study.

Conclusion: The conclusion states that MC is considered a low-frequency STD and emphasizes the impact on visual aesthetics rather than symptoms. It effectively ties back to the objective of the study.

Overall, the abstract provides a clear and concise summary of the study, outlining its objective, methodology, key findings, and conclusion. However, it could benefit from slightly more detail in the methodology section to provide a clearer understanding of how the study was conducted.

Thank you. Kind regards.
