Benign partial epilepsy of infancy with complex partial seizures

INSERM

Source

INSERM. (1999). Orphanet: an online rare disease and orphan drug data base. Benign partial epilepsy of infancy with complex partial seizures. ORPHA:166299

Benign partial epilepsy of infancy with complex partial seizures is a rare infantile epilepsy syndrome characterized by complex partial seizures presenting with motion arrest, decreased responsiveness, staring, automatisms and mild clonic movements, with or without apneas, normal interictal EEG and focal, mostly temporal discharges in ictal EEG. Most often, seizures occur in clusters and have a good response to treatment. Psychomotor development is normal.
