I think the topic is interesting and worth researching. Methodology that the authors used seems reasonable, however, I think the discussion is too little. This is partially because of the amount of data they collect, which was also little. Discussion and comparisons could be made clearer and more in detail. For instance, the explanation for the interactions between antimicrobial compounds and alginate is vague, and should be more certain. And the other issue, for me, is the comparison of different literatures with the authors'. The transitions are too sharp from their own study to the others, and the way of relating is not appropriate. I suggest to revise the manuscript, considering particularly results and discussion part; and if possible add more data points (may be different concentrations of bacteria).
