Review of: "Minor Foreign Bodies Remaining in the Stratum Corneum of the Plantar Skin Are Mistaken for Plantar Fasciitis: A Case Report (Mechanism of Injury Analysis and Literature Review)"

Stephen I. Ternyik¹

1. Spiru Haret University, Romania

This case serves as a reminder for healthcare professionals to assess for foreign bodies in cases of foot injuries, even when the initial presentation may not suggest a complication. Further investigation, including imaging studies if necessary, may be helpful in identifying such retained objects when symptoms persist beyond the expected healing time.

The resolution of pain after the removal of the foreign body suggests that timely intervention is crucial, and it points to the need for education among patients regarding the importance of seeking medical care for penetrating foot injuries. Overall, this case illustrates the complexities associated with soft tissue injuries of the foot and the various factors that can affect a patient's recovery.
