Dear authors,

The topic is important and the basic methods are proper. Something is wrong with the regression ORs, when you look at the figures, the best glycemic control was presented in the group of patients age 40-49, and you choose to compare age subgroups with the last age subgroup (the oldest). Since you have small number of patients in the younger subgroups, I suggested you to merge 30-39 and 40-49 subgroups and to recalculate the ORs using the youngest subgroup as a comparator. Check other regression calculation.
