Potential competing interests: I found no conflict of interest

I think the present manuscript contains valuable information about peatlands and forest vegetation covered them in the studied National park in Vietnam. Although there are several interesting results, the paper is really unorganized and the readers can not follow its goals.

Materials and Methods are not clearly defined and described. For instance, how did the authors measure or estimate seasonal peat changes and a majority of big questions which are not adequately addressed in this work

The authors should employ multivariate analysis in order to better present their data and its interrelationships. The stepwise analysis can be used as well.

Overall, in my point of view, the manuscript should be reorganized and it should be revised majorly based on new statistical approach.
