Hello.

These are the few concerns I would like to address.

1. Rationale of choosing the sample size number has to be mentioned. Applying statistics may not be reliable if sample size is not chosen according to standard statistical formulae.

2. Sampling method used in the study has to be written.

3. Method used to assess adherence to medications has not been clearly defined. please mention if any standard validated questionnaire was used.

4. More parameters could have been assessed for poor glycemic control. for example, insulin usage, other comorbidities, polypharmacy, education level, occupation etc.

5. While analyzing multi variate logistic regression, it is better if you include only the parameters which were significant in binary logistic regression to improve statistical accuracy.

6. In discussion, try providing rationale for poor glycemic control in age group 40-49 years which was found to be significant in the analysis. if unable to come to a discrete reason, would advised to consider variables in binary for the analysis.

if above concerns have been addressed, article looks good to publish. good luck to the authors.
