The COVID-19 pandemic has become a test not only for patients but also for healthcare professionals. As medical workers have a great physical and psychological load, performing work in protective suits only worsens the situation. Therefore, this article is very relevant and necessary to improve the working conditions of health professionals. As you can see from the article, personal protective equipment causes skin problems and creates an additional burden on staff, causing discomfort.

I am an infectious disease doctor, I work with patients with COVID-19 and I also have negative effects related to the use of personal protective equipment. We also conducted similar studies to determine the effectiveness of personal protective equipment and their danger as sources of infection.

For the author of the article, I recommend increasing the number of health professionals of different ages for the study. It is also possible to suggest that some respondents use care products to reduce the negative impact of personal protective equipment and compare with the control group.

It would be interesting to know about the air conditioning system in the hospital where the workers who participated in the study worked and whether they had overheating.

I thank the author of the article for his work. It is very relevant and promising for further research.
