Enlarged parietal foramina

INSERM

Source

INSERM. (1999). Orphanet: an online rare disease and orphan drug data base. Enlarged parietal foramina. ORPHA:60015

Enlarged parietal foramina (EPF) is a developmental defect, characterized by variable intramembranous ossification defects of the parietal bones, which is either asymptomatic, symptomatic (headaches, nausea, vomiting, intellectual disability) or associated with other pathologies.
