This is a detailed case report about the effectiveness of Atlasprofilax method in the treatment of cervical spinal misalignment. However, there are several aspects that the authors can consider to include to improve the quality of this publication:

1. Given this is a case report, it would be better if more details patient condition description can be included. One session treatment effectiveness is supported by this individual case, how it is general or special could affect the conclusion about whether we want escalate the study to a larger scale.
2. Related to the comment above, any patient group that is not indicated to use this method?
3. I'm questioning how long the treatment effect can last since there is very limited post-intervention examination in the report and any side-effects.
