A case of mumps virus pneumonia in a young adult is presented. It is a very rare complication of mumps virus infection in adults, particularly in those without comorbidities.

The basic features of mumps virus infection are well described. The presentation of the case study is adequate and complete also as regards the presentation of the diagnostic tests.

The discussion of the case appears adequate also with reference to what is reported in the literature. It could be interesting, without affecting the publication of the study, to evaluate the specific vaccination history of the case, if possible.
