The authors of this original and very interesting retrospective study described the demographic and clinical characteristics of refugee children who use health services in Turkey and specifically analyzed access data in a university hospital in Istanbul. In my opinion, it is a well-conducted study, and the article that illustrates it is complete in every part. This study has the advantage of informing all European countries that welcome minor refugees, including Italy, on the prevalence of communicable and non-communicable diseases and their health needs. This data could be valuable for useful comparisons with different European realities. The only suggestion to the authors is the following: why don't you try to analyze the data according to the gender of the minor refugees?
