This manuscript “ Planetary relationships as a key signature from the dark sector” has an interesting observation that a planetary dependency requires streaming matter from the dark Universe, since all objects of the solar system are effective gravitational lenses for typical DM velocities and DM searches could also profit from spatiotemporally peaking time intervals appearing in other observations, which might be correlated with a direct DM search. The idea is very intuitive, and the manuscript can be published as partially supported speculation, but it needs more detailed study and rigor to claim these ideas as facts. So, statistically speaking, the study is not detailed or sufficient, but theoretically speaking the idea has merit as possible explanation of the phenomenon and it has logical support.
