Potential competing interests: No potential competing interests to declare.

The title and the summary reflect the main aspects of the paper.

The introduction contains detailed information about the topic and content of the paper, the purpose of the research, but lacks explanation of the key terms (quality of life, social support, mental health, burnout, exhaustion) as an introduction before examples of previous research are presented in the introduction. In this way, the structure of the introduction would be coherent.

The research methods are clearly stated. The instruments used for data collection, the procedure and method of conducting the research, and the data processing are described and well explained. The results obtained are consistent with the methods described.

Recommendation: In the sample, specify the profile of the health professionals involved in the research (doctors, nurses, etc.).

The authors connect the results obtained with the research findings of other authors.

The information obtained is very useful. As the research shows, there is a problem of fatigue and exhaustion (physical and mental) among the respondents, as well as a low level of perceived social support, which can lead to serious health problems and at the same time to a lower quality of health care. The research findings are of great importance in the search for the best support models for healthcare workers and the implementation of preventive measures at both the individual and organizational (work environment) levels.

The figures and tables are clear and easy to read and accompany the text.

The analysis is appropriate and relevant to the research, as is the presentation of the data. The references are properly cited in the paper.

The conclusion presents the results obtained in a concise and clear manner.
