Thank you for inviting me to review this paper.

Overall, an interesting study reflecting the need to assess the preoperative nutritional status of patients in the hospital setting.

However, the fact that this study was carried out in wards that did not manage digestive pathologies could explain the fact that the majority of patients had a normal BMI... Could this be explained and discussed further?

In the methods, detail what type of healthcare staff was involved: doctor, nurse... (?) even if this is specified in the results; however, doesn't this represent a bias? In this case, try to explain everyone's role in assessing the nutritional status in the hospital setting.

Otherwise, the work itself, especially the implementation, is very interesting. Congratulations to the authors.
