**Potential competing interests:** No potential competing interests to declare.

This theoretical work focuses on the genetic and environmental factors in personality development. However, given the current emphasis on empirical studies, incorporating at least two different approaches would strengthen the research.

Suggested approaches include:

- a) A review paper based on the author's original research on the topic.
- b) A meta-analysis or other quantitative analysis of existing works on the specific relationship between genetic and environmental factors in personality development.

To provide a more comprehensive presentation, include an overview of relevant personality models. This step would help establish a clear theoretical framework and demonstrate a connection to the dominant paradigm on which the author relies. Ensure a more comprehensive and clear structure for the work. The introduction should contain a well-defined research question or hypothesis, and subsequent sections should follow a logical flow. Consider incorporating a brief overview or roadmap of the article in the introduction to guide the reader through the content.

Emphasize the importance of adhering to scientific rigor. Clarify the methodological details, including the search criteria, inclusion/exclusion criteria for studies, and the process of study selection. Address potential biases in the selected studies and discuss their implications for the overall conclusions. The conclusion should effectively summarize the main findings and their significance for the research question. Reiterate the contributions of the study and highlight the implications for future research in the field.

By addressing these specific points, the theoretical work can be more effectively structured, grounded in existing research, and aligned with the expectations for scientific rigor in the current academic landscape.
