The aim of this study is to observe whether there is a gender disparity in hospital treatment based on gender. I would like to know what led to the analysis of this issue.

I would like to know whether there is a problem of differences in treatment based on gender in other infectious or endemic diseases. The study groups were created and conducted in order to minimize differences in income and education.

The question is whether this sample is representative of the population, or whether the study aims to analyze the difference in treatment only in relation to gender. In this case, I would like to ask the initial question about the reason for this problem and this mosquito-transmitted disease. I would like to see these issues clarified in order to understand the object and the problem of the study.

According to my review, the authors could present evidence of differences in treatment in other communicable and/or endemic diseases. They could provide evidence whether the samples are representative of the population, namely differences in mortality or morbidity by gender due to dengue fever.
