The article is well written with an objective to understand the choice of women in Nepal towards healthcare system (public/private). I would like to stick to my comments on statistical analysis. The p values written as 0.000 should be corrected to rewrite as $p < 0.001$. The tables with bivariate and "multivariate" findings seem exactly the same when it comes to aOR. I want to understand what the authors intend by aOR in bivariate table? In bivariate table, What are these ORs adjusted for? Also, the term multivariate is wrong. Instead use a term multivariable, as we have one single outcome/response and multiple independent variables
