In the age of user-generated data, sentiment analysis can provide structures to shed light, analyse, and make sense of abundant information. This paper aims at increasing understanding and making sense by implementing Sentiment Analysis over social media platforms and exploring related compositions between 2015 - 2022. The results of the research can be utilised in diverse contexts to predict the sentiments of tweets, and make predictions for long-term goals in terms of policymaking, and thus, it contributes to the overall research. The abstract needs a better structure that reflects the paper's content and main findings. The mixed methodology used, social media mining and sentiment analysis, as appropriate to the study's aim and objectives. However, the manuscript structure does not follow the scientific structure with specific data presentation, analysis, results extracted and discussed, appropriate conclusions, and implications for the research. In other words, it needs more work on following the scientific structures (rather than a book chapter) and more information and data presentation, analysis, and discussion as well as locating and comparing the results within the field of other related studies.
