**Potential competing interests:** No potential competing interests to declare.

The paper is very interesting, but it does not present the main global indicators on climate change, some of which are: Land and marine protected areas (% of total land area), Renewable energy consumption (% of total final energy consumption), Population growth (% per year), CO2 emissions (kt, metric tons per capita), Total greenhouse gas emissions (kt CO2 equivalent), Methane emissions (kt CO2 equivalent), Nitrous oxide emissions (thousand metric tons of CO2 equivalent), Renewable electricity production (% of total electricity production), Energy use (kg of oil equivalent per capita). It would also be useful to measure each country in relation to the rest by publishing the position in the various rankings. Finally, it is important to include the source of the data.
