Background

This is a good article on an important topic. The coexistence of non-communicable diseases (NCDs) with HIV can have significant implications and is worth investigating.

Methods

Although the study comprehensively describes data collection methods for most variables, the dietary assessment methods are not adequately described. For instance, what tool was used for the assessment – 24-hour recall? Food frequency questionnaire? All dietary assessment methods have inherent limitations, thus making it important to adequately describe the methods and their inherent limitations.

Results

Table 3 seems a bit difficult to interpret. It seems likely that there were study participants who had more than one NCD coexisting with HIV? The study is silent on multiple NCDs coexisting with HIV in study respondents and their implications.

Discussion

There is a repetition of results in the first paragraph of the discussion.

Conclusion

The conclusions are based on the objectives and findings of the study. The recommendations drawn were guided by the study results.
