Potential competing interests: No potential competing interests to declare.

The paper makes a notable addition to the current discussion on the convergence of artificial intelligence and the disparity in healthcare. In fact, the paper carefully examines the contrast between the widespread availability of AI applications and the high resource demand for sophisticated health technologies.

The work excels in its relevance, its comprehensive examination of the significance of empathy in patient care, and its competent use of statistical data to support its claims.

The study could be improved by including a more comprehensive global perspective, with a specific focus on the ramifications of AI inequalities in poor and middle-income countries. One might reasonably consider including case studies and/or real-world examples in order to provide concrete evidence to support theoretical discussions. It would also be useful to write a comprehensive conclusion that presents specific recommendations for effectively addressing the inequalities mentioned above.

In order to further improve the paper, it's recommended to expand the scope of the literature review by including contemporary research and opposing viewpoints. In addition, a more explicit explanation of the research technique or analytical approach, if relevant, would further enhance the scientific rigor of the paper.

The paper is very insightful and raises significant ethical and social inquiries, making it a noteworthy contribution to the academic and policy dialogue on AI in health care.
