Potential competing interests: No potential competing interests to declare.

The present study addresses a central topic of extreme importance for health in all societies, especially in developing countries. It is a strategy for the primary prevention of highly effective diseases in health, with significant socioeconomic relevance. The authors presented a consistent and clarifying introductory content on the relevance of the problem addressed. Both the research hypothesis and the pre-established objectives are appropriate and congruent with each other. The entire methodological process was developed with high scientific rigor. From the sample determination of data collection, in addition to the analysis of their statistics, it was carried out appropriately and apparently free from biased actions. The fact allows us to infer the opinion that the incidence of possible biases intrinsic to this type of studies has been strongly minimized. The session to present the results and discuss current literary content is also conducted appropriately. Finally, the authors present appropriate final considerations consistent with the results obtained. In addition to also presenting critical and constructive suggestions for the application of data and the development of new studies. Given the facts, I consider the present study suitable to be published as is.
