Pemphigus erythematosus

INSERM

Source

INSERM. (1999). *Orphanet: an online rare disease and orphan drug data base*. *Pemphigus erythematosus*. ORPHA:79480

Pemphigus erythematosus is a rare superficial pemphigus disease characterized clinically by well-demarcated, localized, erythematous, scaly, hyperkeratotic, crusted plaques, with frequent butterfly distribution over the malar area of the face (but also commonly involving trunk and scalp, and less frequently the extremities, with a photoexposed distribution). Histologically, granular deposits along the dermal-epidermal junction, in addition to intercellular deposition in the upper epidermis, are observed.
