The manuscript has some value and I think it is worth publishing but some major flaws are recognized. Introduction is more oriented to the general problem of GHG emissions and lacks information about what is the problem you are addressing. In sixth paragraph of the Introduction, you are already stating what is the main source of GHG emissions during cotton production, something that you conclude at the end. I don't see something truly innovative in your study. Simple quantification of the GHG emissions fine (provided data, time scope of study, geographical differences between the plots etc, that is all enough for some initial investigation, further improvement in terms of LCI is something that I would suggest) but your focus definitely should be what do you want to do with the results of this research and try to make a better goal of the study.
