The article "The imperative of a comprehensive One Health approach for mosquito-borne disease control in Indonesia" advocates strongly for the application of One Health methodologies for improving control of mosquitoes and mosquito-borne disease in Indonesia. As a principal, such approaches are generally welcome, although the author did not explicitly explain how the application of 1H would directly achieve this. As other reviewers have pointed out, the article would benefit from data on the current situation, trends, and burden (human, animal, economic) to emphasise the need and focus for further measures. And it will be further measures, so cost/benefit analysis is important to focus the minds of policy makers. A further concern is the biology/epidemiology behind the diseases mentioned (Zika, dengue, chikungunya, malaria); it's not clear what the animal involvement in these diseases is. Perhaps the inclusion of entomologists, hydrologists, and town planners might be of more value in combating these diseases in high-density population settings.
