**Potential competing interests:** No potential competing interests to declare.

Talking about post-COVID-19 syndrome is relevant because the literature to date tells us that patients affected by this sequel have a decrease in road quality. The most frequent phenotype is well typified, however, in the Mexican population there is a lack of accurate information since we only have series of cases or descriptive studies, even if it is of medical interest to know the behavior and the recapitulation of all this data is very useful.

I consider it important in the data collection table to write down a column with the age and in the symptoms section those not previously described by post-COVID-19 syndrome and for which symptoms of the patient's underlying disease/comorbidity should be eliminated. Such is the case of the cohort of CMN patients.
